(2010-04-28 08:46:09).Reduced flow-mediated dilation after continuous smoking--apnea and incident coronary heart disease. The flow-mediated dilation (FMD) is a validated noninvasive method to assess vascular function and predict coronary heart disease (CHD) risk. We investigated the flow-mediated dilation in smokers and continuous smokers, and identified predictors and potential mechanisms of impaired FMD response. The smoking status of patients with prior coronary artery bypass graft surgery or angina pectoris was investigated. A noninvasive vascular laboratory measured the FMD response in smokers (n = 67) and continuous smokers (n = 30) at baseline, after a smoking cessation of 5 days, and at a follow-up of 6 to 12 months after the baseline visit. The continuous smokers revealed a higher baseline FMD compared with the smokers (P =.026), and an impaired FMD response at follow-up after 6 to 12 months of continuous smoking was found (P =.005). Continuous smokers had the highest percentage of patients with a reduced FMD
