This is three orders of magnitude faster than the half-life of P3HT in water. The fact that P3HT conjugated with NBD is photoswitchable is very interesting, not least because it should be possible to develop photo-addressable polymers with a range of excited state properties from fast (ns) to slow ( $\mu$ s). Perhaps the most important thing from a practical perspective is that the half-life of P3HT in the solid state is so much shorter than in aqueous solution, although we cannot say whether the faster solid state is due to a rate limiting process in the bulk or not. The photochemical behaviour of NBD-conjugated P3HT in CsCl, is shown in figure 1. The data were acquired as the polymer

---

was illuminated at  $\lambda_{\text{ex}} = 387$  nm. It is evident that after 1 s of illumination the fluorescence ( $\lambda_{\text{em}} = 530$  nm) of the polymer has fallen to about 1% of its original value. This decay rate is similar to that observed for all other photophysical properties of P3HT, including UV/Vis absorption and steady-state fluorescence emission. Fig. 1: Normalised fluorescence intensity of the photoswitchable polymer NBD-P3HT in CsCl as a function of time for  $\lambda_{\text{ex}} = 387$  nm. Using UV/Vis absorption measurements we were able to measure the concentration of polymer in solution as a function of time. The concentration-time profiles were acquired on a Cary 100 spectrophotometer. We observe that the absorption maximum increases with time with a rate constant of  $0.022 \text{ s}^{-1}$ . The data show that the concentration of the polymer increases by about  $1 \times 10^{-3}\%$  over the course of the experiment, giving a growth rate of  $0.54 \mu\text{M min}^{-1}$

system tools system tools version 2018.1.220 telerik ui for winforms r1 2018 sp1 the kane chronicles survival guide pdf Heparin is an injectable anticoagulant used in medicine to prevent or treat clotting in a patient. The anticoagulant effect of heparin is mainly achieved by inhibiting the activity of a factor that is also known as thrombin activatable fibrinolysis inhibitor (TAFI),

---

which is present on the surface of blood platelets and is bound to the extracellular matrix. Inhibition of TAFI activity by heparin contributes to the anticoagulant effect of heparin. Chemically, heparin is an oligosaccharide. Heparin is derived from the mast cells of cattle, and it has been purified from naturally-occurring animal intestinal mucosal heparin. A polysaccharide with similar biological effects can be derived from N-sulfated glucosamine derived from soybean mucin. Heparin is a heterogeneous mixture of compounds including L-iduronic acid and D-glucosamine. Most commonly, the structure consists of a linear chain of alternating L-iduronic acid and N-sulfated D-glucosamine residues joined by alternating  $\alpha$ -1,4 and  $\alpha$ -1,3 glycosidic bonds. In neutral pH, at least two non-linear chains with alternating D-glucosamine and N-sulfated D-glucosamine residues are typically present, usually involving two or three sulfate groups. For example, in heparin extracted from porcine intestinal mucosa, the structure consists of approximately 40 L-iduronic acid residues and approximately 100 N-sulfated D-glucosamine residues linked by  $\alpha$ -1,4- and  $\alpha$ -1,3-glycosidic bonds. In acidic pH, the non-reducing terminal groups are sulfated. In addition, less acidic sugars are also present in the heparin chains and some of

---

them are sulfated. Heparin can also be prepared from partially depolymerized heparin having approximately 15
